BACKGROUND OF THE INVENTION

10 This invention relates to mono-substituted 5H-2,3-benzodiazepine
compounds useful as antagonists of excitatory amino acid receptors.

 During the past twenty-five years a great deal of attention has been
directed toward the excitatory amino acids (EAA's), glutamate and aspartate,
since they are believed to be the neurotransmitters responsible for the fast
excitatory transmission in the mammalian central nervous system. The
15 ionotropic EAA receptors are generally sub-classified into NMDA and non-
NMDA receptors. These classifications are defined by those receptors which
preferentially bind N-methyl-D-aspartate (NMDA) and those that are not
responsive to NMDA but responsive to α -amino-3-hydroxy-5-methyl-4-
isoxazolepropionic acid (AMPA) or kainic acid (KA).

20 Tarnawa *et al*, describe 2,3-benzodiazepines (*Eur. J. Pharmacol.*,
167:193-199, 1989) which inhibit AMPA stimulated currents in neuronal
cells. The 2,3-benzodiazepines such as GYKI 52466 and 53655 described by
Tarnawa are non-competitive AMPA antagonists which bind to a novel
modulatory site on the AMPA receptor. Meldrum (*Stroke*, 23:861, 1992 &
25 *Brain Res.*, 571:115, 1992) has shown that GYKI 52466 is effective in rat
models of both global and focal ischemia. GYKI 52466 was effective in a
middle cerebral artery occlusion (MCAO) model of ischemia when given
either continuously for 2 hours just after occlusion or delayed for one hour.
The compounds reduced cortical infarct volumes by 68% and 48%
30 respectively. In another model of neurodegenerative disease, GYKI 52466
was as effective as the glutamate site competitive antagonist NBQX in rat
common carotid arteries model of global ischemia. These two animal

models suggest that these compounds may be useful for the treatment of stroke and neurodegenerative ischemic conditions.

Efforts to find NMDA receptor antagonists and blockers which are neuroprotective have been very successful while efforts to find specific non-
5 NMDA receptor antagonists have been much less successful. A number of pharmaceutical companies have pursued development of ion channel blockers or full antagonists of the NMDA receptor to protect against both chronic and acute neurodegenerative processes. Although some compounds have entered clinical trials, there has been only limited progress in
10 developing a clinically useful NMDA receptor antagonist. Some useful compounds, namely substituted dihydrophthalazines, have been described for use as non-NMDA receptor antagonists (U.S. Patent No. 5,716,956). These compounds are particularly useful because they bind selectively to AMPA receptors. Moreover, 5H-2,3-benzodiazepine AMPA antagonists have been
15 described by Tarnawa, et al. (Amino Acids: Chemistry, Biology and Medicine, Lubec, G., Rosenthal, G.A., Eds.; 1990 p. 538).

It is an object of the invention to provide compounds which are useful as non-NMDA glutamate receptor antagonists as well as methods for their synthesis.

20 It is a further object of the invention to provide non-NMDA receptor antagonists which are useful as sedatives or for the treatment of neuropsychopharmacological disorders such as stroke, ischemia and epilepsy.

It is yet another object of the invention to provide compounds which
25 are useful for the treatment of neurological, neuropsychiatric, neurogenerative and functional disorders associated with excessive activation of the non-NMDA subtypes of the ionotropic EAA receptor.

BRIEF SUMMARY OF THE INVENTION

Compositions are provided which are active as non-NMDA
30 ionotropic excitatory amino acid (EAA) receptor antagonists, in particular, which bind to the AMPA receptors, and which therefore are useful for treating disorders associated with excessive activation of the non-NMDA

subtypes of the ionotropic EAA receptors. The compounds further are useful as testing agents to identify and characterize other compounds for the treatment of these disorders. The disclosed compounds are 7- or 8- mono substituted 5*H*-2,3-benzodiazepines.

DETAILED DESCRIPTION OF THE INVENTION

I. Glossary of Terms.

The term "**antagonist**" as used herein means any compound which reduces the flow of ions through the non-NMDA receptor.

The term "**neuropsychopharmacological disorder**" as used herein means a disorder resulting from or associated with an excessive flux of ions through the AMPA receptor ligand-gated cation channels, and includes chemical toxicity (including substance tolerance and addiction), excitotoxicity, neurodegenerative disorders (such as Huntington's disease, Parkinson's disease, and Alzheimer's disease), post-stroke sequelae, epilepsy, seizures, mood disorders (such as bipolar disorder, dysthymia, and seasonal affective disorder), and depression. Neurodegenerative disorders can result from dysfunction or malfunction of the AMPA receptor.

30 The term "**NMDA receptor**" as used herein means a receptor which is stimulated, at a minimum, by the excitatory amino acids glutamic acid as

well as by NMDA, but is not stimulated by AMPA or KA. It is a ligand-gated receptor.

5 The term "**AMPA receptor**" as used herein means a receptor which is stimulated, at a minimum, by the excitatory amino acids glutamic acid as well as by AMPA, but is not stimulated by NMDA. It is a ligand-gated receptor.

10 The term "**Kainate receptor**" as used herein means a receptor which is stimulated, at a minimum, by the excitatory amino acids glutamic acid as well as by KA, but is not stimulated by NMDA or AMPA. It is a ligand-gated receptor.

15 The term "**activation**" as used herein in reference to neurotransmitter receptors means the opening of an ion channel to transfer an electric signal generated by an ion flux through the channel. The activation level of receptors can be altered by the disclosed compounds. The term "**excessive activation**" refers to an activation that the opening of an ion channel for a prolonged period of time so that there is an excessive ion flux through the channel, which results in substantial damages to the cell including cell death.

20 Throughout this application when an alkyl substituent is identified, the normal alkyl structure is intended (i.e. butyl is n-butyl) unless otherwise specified. However, when radicals are identified (e.g. R⁵), both branched and straight chains are included in the definition of alkyl, alkenyl, and alkynyl.

III. Synthesis

The compounds of Formula I or II may be prepared using synthetic
10 reactions and techniques available in the art, as described, for example in March, "Advanced Organic Chemistry," 4th Edition, 1992, Wiley-Interscience Publication, New York. The reactions are performed in solvents suitable to the reagents and materials employed and suitable for the transformation being effected. Depending upon the synthetic route selected,
15 and the functionality of the starting material or intermediates, the appropriate protection groups and deprotection conditions available in the art of organic synthesis may be utilized in the synthesis of the compound.

In one embodiment, compounds of Formula I and II may be synthesized as outlined in Schemes 1-3.

IV. *In Vitro* And *In Vivo* Assays Of Activity And Therapeutic Efficacy

In vivo and *in vitro* assays may be conducted to determine the activity of the compounds as antagonists of the non-NMDA receptors, *i.e.*, the ionotropic EAA receptors which bind AMPA or KA. In combination, *in vitro* and *in vivo* assays are predictive of the activity of these compounds for

10

treatment of patients. This is supported, for example, by numerous studies in the literature illustrating that *in vitro* and *in vivo* studies of NMDA receptor modulation by a test compound provide a good indication of the compound's efficacy in treating disorders associated with excessive activation of the NMDA receptor. See, for example: Meldrum, *Epilepsy Research*, 12:189-196 (1992); Lipton and Rosenberg, *New England Journal of Medicine*, 330:613-622 (1994); and McBurney, *Neurobiology of Aging*, 15:271-273 (1994).

A. Electrophysiology

The potency of the disclosed compounds for drug inhibition of the AMPA receptor can be tested using the whole-cell patch clamp technique on primary cultures of rat neocortex. The general procedure for stimulating AMPA-receptor mediated currents with KA and for the measurement of current inhibition is based on that used by Donevan and Rogawski (*Neuron*, 10: 51-59, 1993) for 2,3-benzodiazepines.

Standard extracellular bath solutions and intracellular pipette solutions are used as described in detail by Hussy and coworkers (*J. Physiol. (Lond.)*, 481.2: 311-323, 1994). The drug application system is designed to allow rapid switching between 7 different reservoirs containing either control bath solution, kainic acid (50 μ M), or kainic acid (50 μ M) plus antagonist (10 μ M). Each recording is begun with a control response to KA alone.

Following the establishment of a 2-3 sec duration steady baseline, bathing solution is switched to one containing KA plus antagonist for an additional 2-3 sec period. Alternatively, 5 different doses of a single compound are tested for the determination of the antagonist IC₅₀.

B. Neurodegenerative Transient Global Forebrain Ischemia

The extent of protection by a test compound in a model of brain ischemia may be assayed as described by Meldrum *et al.* (*Brain Res.*, 571:115, 1992), and references cited therein. Male Wistar rats (250-300 g) are anesthetized using halothane-oxygen-nitrogen mixture and both vertebral arteries are permanently occluded by electrocauterisation within the alar foraminae of the first cervical vertebra. At the same time, both common

carotid arteries are isolated and atraumatic clamps placed around each one. One femoral vein is cannulated to enable the subsequent iv administration of fluid. The following day cerebral ischemia is induced in the unanaesthetised animal, by tightening the clamps around the carotid arteries for 20 min.

- 5 Carotid clamping results. Body temperature is maintained at 37°C by use of a rectal probe and hot plate. Seven days after the ischemic insult rats are sacrificed and the brains processed for light microscopy. Neuroprotection is assessed by examination of the extent of damage in the cortex and hippocampus. Compounds may be selected which are active in this model.

10 **C. Neurodegenerative Permanent Focal Ischemia**

- The extent of protection by a test compound in a model of brain ischemia may be tested using a model described by Meldrum and Smith (*Stroke*, 23:861, 1992), and references cited therein. Male Fisher F344 rats (210-310 g) are anesthetized with halothane-oxygen-nitrogen mixture receive
15 a small incision between the eye and ear, the mandibular muscles are retracted to expose the orbit and zygomatic arch. A small craniotomy is made to expose the base of the middle cerebral artery. Bipolar coagulation is used to permanently occlude the artery at the base. One day after the ischemic insult rats are sacrificed and the brains processed for light
20 microscopic examination. Lesion volume is determined by using Cavalarei's principle. Compounds may be selected which are active in this model.

D. Maximum Electro Shock (MES) Seizure Test

- The extent of protection by a test compound in a seizure model is tested as described by Rogawski *et al.* (*Epilepsy Research*, 15:179-184, 1993). Male NIH Swiss mice (25-30 g) are injected ip with the test drug.
25 The mice are subjected to a 0.2 sec, 60 Hz, 50 mA electrical stimulus delivered with corneal electrodes wetted with 0.9% saline at 15-30 min post dosing. Animals failing to show tonic hind limb extension are scored as protected. Compounds may be selected which are active in this model.

30 **E. Subcutaneous Metrazol (scMET) Seizure Test**

This test can be used to determine the extent of protection by a test compound in a seizure model. The method used is that of Chen *et al.* (*Proc.*

Soc. Exp. Biol. Med., 87:334, 1954). Mice are randomly assigned to vehicle or treatment groups of 3-10 animals per group and then dosed accordingly. Metrazol (pentylenetetrazol) 90 mg/kg is administered subcutaneously (sc) at different time points (0.25, 0.5, 1, 2, 4 hr) after the treatment or control groups . The mice individually housed in clear runs and observed for the presence or absence of clonic seizure activity (>5 s duration) for 30 min after metrazol dosing. A compound is considered active if no seizure is observed. Data is analyzed using a quantal measure (protection/number tested).

V. Dosage Forms

The disclosed compounds can be administered parenterally, that is, subcutaneously, intramuscularly, or intravenously and, alternatively, administered orally, in a dose range of between about 0.01 and 100 mg/kg body weight.

The active ingredient can be administered parenterally in sterile liquid dosage forms. In general, water, a suitable oil, saline, aqueous dextrose, and related sugar solutions and glycols such as propylene glycol or polyethylene glycols are suitable carriers for parenteral solutions. Solutions for parenteral administration preferably contain a water soluble form of the active ingredient, suitable stabilizing agents, and, if necessary, buffer substances. Antioxidizing agents such as sodium bisulfite, sodium sulfite, or ascorbic acid either alone or combined are suitable stabilizing agents. Also used are citric acid and its salts and sodium EDTA. In addition, parenteral solutions can contain preservatives, such as benzalkonium chloride, methyl- or propylparaben, and chlorobutanol.

The active ingredient can be administered orally in solid dosage forms, such as capsules, tablets and powders, or in liquid dosage forms, such as elixirs, syrups, and suspensions. Gelatin capsules contain the active ingredient and powdered carriers, such as lactose, starch, cellulose derivatives, magnesium stearate, stearic acid, and the like. Similar diluents can be used to make compressed tablets. Both tablets and capsules can be manufactured as sustained release products to provide for continuous release of medication over a period of hours. The active ingredients also may be

provided in a particle for sustained or pulsed delivery such as a liposome or microcapsule. Compressed tablets can be sugar coated or film coated to mask any unpleasant taste and protect the tablet from the atmosphere, or enteric coated for selective disintegration in the gastrointestinal tract. Liquid dosage forms for oral administration can contain coloring and flavoring to increase patient acceptance. Suitable pharmaceutical carriers are described in Remington's Pharmaceutical Sciences, a standard reference text in this field.

Optionally, the compounds either alone or in combination with a carrier may be administered by implantation or by application to a mucosal surface, for example, the nasal-pharyngeal region and/or lungs using an aerosol or may be administered to a skin surface via a topical carrier such as a cream or lotion.

The compounds of this invention and their preparation can be understood further by the following non-limiting examples which describe the synthesis of exemplary compounds. In these examples, unless otherwise indicated, all temperatures are in degrees Celsius and parts and percentages are by weight.

Example 28: *In Vitro* And *In Vivo* Tests for Inhibition of Ca^{2+} Influx into Cortical Cells Stimulated with AMPA

Three of the antagonists disclosed herein were tested, *in vitro*, for inhibition of Ca^{2+} influx into cortical cells stimulated with AMPA. They are 1-(4-Aminophenyl)-3,5-dihydro-4-methyl-3-acetyl-7-methoxy-5H-2,3-benzodiazepine (**8**) (SYM 2267), 1-(4-Aminophenyl)-3,5-dihydro-4-methyl-3-acetyl-8-methoxy-5H-2,3-benzodiazepine (**21**) (SYM 2268), and 1-(4-Aminophenyl)-3,5-dihydro-4-methyl-3-acetyl-7-amino-8-methoxy-5H-2,3-benzodiazepine (**27**) (SYM 2269), respectively. The *in vitro* test measures inhibition of Ca^{2+} influx into cortical cells stimulated with 50 M AMPA by the test compounds. The rationale underlying this assay is that stimulation of the cortical cells with AMPA activates AMPA receptors causing Ca^{2+} influx with an increase in intracellular Ca^{2+} which is then detected by measuring an increase in fluorescence. The Ca^{2+} increase comes mostly from extracellular (influx of Ca^{2+} through the channel into the cell), but could also come from intracellular sources (release of Ca^{2+} from storage). The inhibition of the AMPA receptor function is detected by a decrease in the level of intracellular Ca^{2+} and a decrease in fluorescence. The results are summarized in Table 1.

Table 1. Inhibition of Ca^{2+} Influx into Cortical Cells with 50 μM AMPA

Compound	IC_{50} (μM)
SYM 2267	26.1
SYM 2268	16.6
SYM 2269	7.3

Of the three compounds tested, SYM 2269 ($\text{IC}_{50} = 7.3 \mu\text{M}$) is the most potent one for inhibiting AMPA receptor function on cortical neurons in culture. SYM 2267 was evaluated for *in vivo* anticonvulsant activity in the maximal electro shock (MES) model in rats. The rats were given the compound orally (PO) and were found to be fully protected from the MES seizures at 30 mg/kg. No sedative or toxic side effects were observed in the rotorod test. Further tests indicated that SYM 2267 has a MES effective dosage of 8.4 mg/kg ($\text{ED}_{50} = 8.4 \text{ mg/kg}$).
